

Introduction to Scripting “Bash”

<https://github.com/BilalMaz/DevOps-Architect-BootCamp>

About me

Hi there, my name is Bilal and I will Welcome you to DevOps boot camp! I am thrilled to have you join us for this exciting journey of learning and discovery.

In this boot camp, we will be exploring the principles and practices of DevOps, which is a set of methodologies and tools that aims to bridge the gap between software development and operations. DevOps is an increasingly important area in the field of software engineering, as it helps organizations to streamline their processes, improve their agility, and deliver better value to their customers.

By the end of this boot camp, you will have gained a comprehensive understanding of DevOps and its key concepts, as well as practical skills in areas such as infrastructure automation, continuous integration and delivery, monitoring and logging, and more. You will be equipped with the knowledge and tools to apply DevOps principles in your own work and contribute to the success of your organization.

I am always looking to connect with other professionals in the field, share ideas and insights, and stay up to date on the latest trends and developments. I welcome the opportunity to connect with you and explore ways in which we can collaborate and support each other.

What is scripting in Linux ?

A script is essentially a program written in a scripting language, such as Bash, Python, Perl, or Ruby, which can automate tasks or perform complex operations. Scripts are generally used for tasks such as system administration, file management, software installation, and automation of repetitive tasks.

The most common scripting language used in Linux is Bash (Bourne Again SHell), which is a command-line interpreter and scripting language that comes pre-installed with most Linux distributions. Bash scripts can be created using a simple text editor, such as Vim or Nano, and can be run using the terminal or command line interface.

Bash

Bash is a shell or a command-line interpreter that is commonly used in Linux and other Unix-like operating systems. It is the default shell for most Linux distributions and is used to execute commands, run scripts, and interact with the operating system. Bash stands for "Bourne-Again SHell," which is a reference to the Bourne shell, an earlier Unix shell that Bash was based on.

Bash is the default shell in Linux, other shells like Zsh, Ksh, and Tcsh are also available and can be installed and used. However, Bash is the most commonly used shell, and most Linux tutorials and scripts assume the use of Bash.

Type of Shell ?

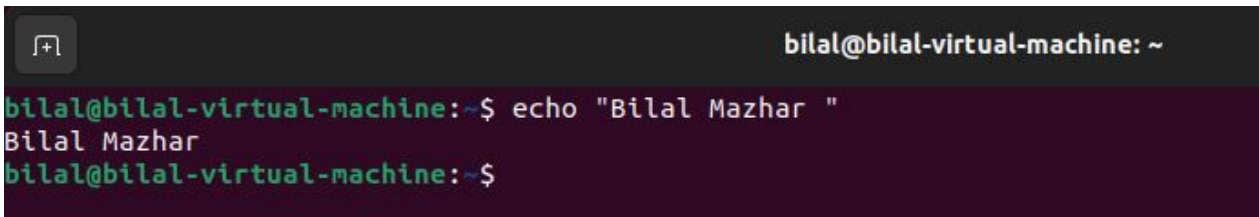

There are several shells available in Linux, including:

- Bash (Bourne-Again SHell) - This is the default shell for most Linux distributions and is the most widely used shell in Linux. It is an enhanced version of the original Bourne shell and provides features such as command line editing, history, and job control.
- Csh (C SHell) - This is a shell that provides a C-like syntax and is popular among programmers who are used to the C programming language.
- Tcsh (TENEX C Shell) - This is an enhanced version of the C shell and provides features such as command-line editing, history, and job control.
- Zsh (Z SHell) - This is an interactive shell that is designed to be more user-friendly and customizable than Bash. It provides advanced features such as spelling correction, path expansion, and file globbing.
- Dash (Debian Almquist Shell) - This is a minimal shell that is designed to be fast and efficient. It is commonly used as the default system shell in many Linux distributions.
- Ksh (Korn SHell) - This is a shell that provides a combination of features from the Bourne shell and the C shell. It is widely used in commercial Unix environments.

Hello World

1. Interactive Shell: An interactive shell in Linux refers to a shell that allows a user to enter commands and receive immediate feedback in real-time. The interactive shell is typically used in a terminal window or console where a user types in commands to interact with the operating system.

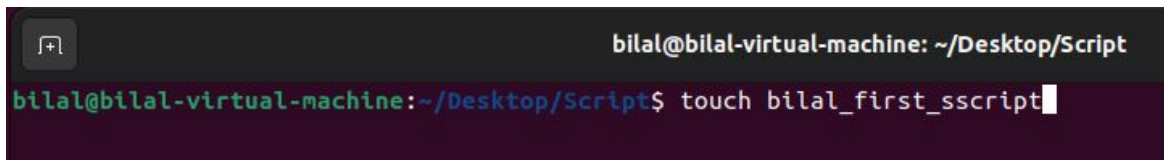

```
bilal@bilal-virtual-machine: ~  
bilal@bilal-virtual-machine:~$ echo "Bilal Mazhar "  
Bilal Mazhar  
bilal@bilal-virtual-machine:~$
```

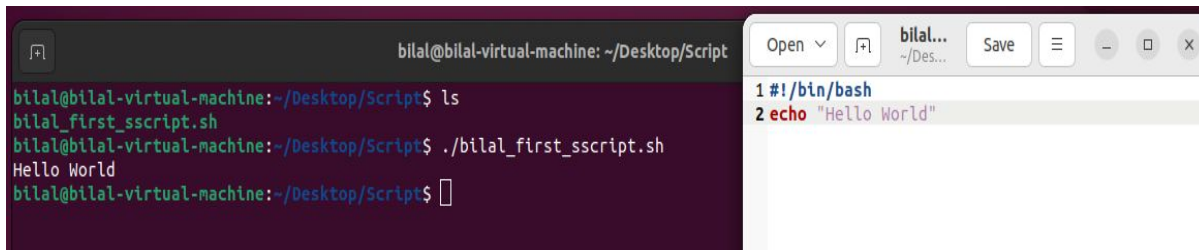

- echo is a Bash builtin command that writes the arguments it receives to the standard output. It appends a newline to the output, by default

Non-Interactive Shell

1. The Bash shell can also be run non-interactively from a script, making the shell require no human interaction. Interactive behavior and scripted behavior should be identical – an important design consideration of Unix V7 Bourne shell and transitively Bash. Therefore anything that can be done at the command line can be put in a script file for reuse.

```
bilal@bilal-virtual-machine: ~/Desktop/Script
bilal@bilal-virtual-machine:~/Desktop/Script$ touch bilal_first_sscript
```

```
bilal@bilal-virtual-machine: ~/Desktop/Script
bilal@bilal-virtual-machine:~/Desktop/Script$ ls
bilal_first_sscript.sh
bilal@bilal-virtual-machine:~/Desktop/Script$ ./bilal_first_sscript.sh
Hello World
bilal@bilal-virtual-machine:~/Desktop/Script$
```

```
1 #!/bin/bash
2 echo "Hello World"
```

Change permission

- `chmod +x` is a command used in Unix-based operating systems to change the permissions of a file, making it executable.
- The `chmod` command is used to modify the permissions of files or directories. The `+x` option is used to add the execute permission to a file, allowing the user to run the file as a program.

```
bilal@bilal-virtual-machine: ~/Desktop/Script
bilal@bilal-virtual-machine:~/Desktop/Script$ chmod +x bilal_first_sscript.sh
bilal@bilal-virtual-machine:~/Desktop/Script$
```

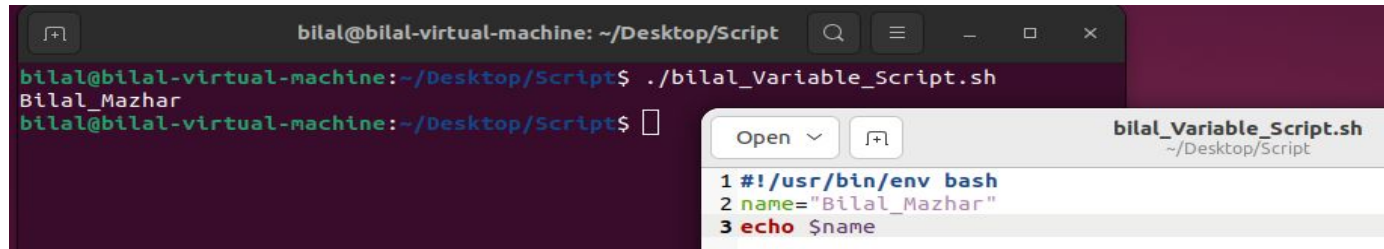

Variable

In Bash, a variable is a name that represents a value. A variable can hold a variety of data types, such as numbers, strings, arrays, and more.

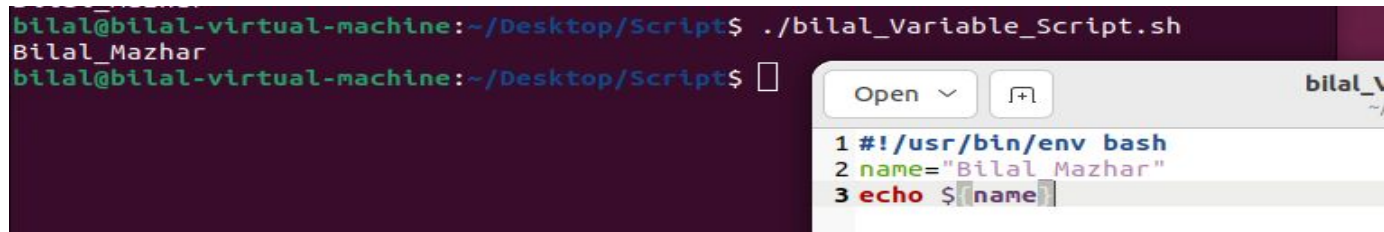

Example	Command
To define a variable in Bash, you simply give it a name and assign a value to it. Here's the basic syntax	<code>variable_name=value</code>
To define a variable called "name" with a value of "John", you would use the following command	<code>echo \$name</code>
To access the value of a variable, you use the variable name with a dollar sign prefix. For example, to print the value of the "name" variable, you would use the following command	<code>echo \${name}</code>

Example

A terminal window titled "bilal@bilal-virtual-machine: ~/Desktop/Script" shows the execution of a script. The prompt is "bilal@bilal-virtual-machine:~/Desktop/Script\$". The command ". /bilal_Variable_Script.sh" is entered, and the output is "Bilal_Mazhar". Below the terminal, a preview of the script "bilal_Variable_Script.sh" is shown with the following content:

```
1 #!/usr/bin/env bash
2 name="Bilal_Mazhar"
3 echo $name
```

A terminal window titled "bilal@bilal-virtual-machine: ~/Desktop/Script" shows the execution of a script. The prompt is "bilal@bilal-virtual-machine:~/Desktop/Script\$". The command ". /bilal_Variable_Script.sh" is entered, and the output is "Bilal_Mazhar". Below the terminal, a preview of the script "bilal_Variable_Script.sh" is shown with the following content:

```
1 #!/usr/bin/env bash
2 name="Bilal_Mazhar"
3 echo ${name}
```

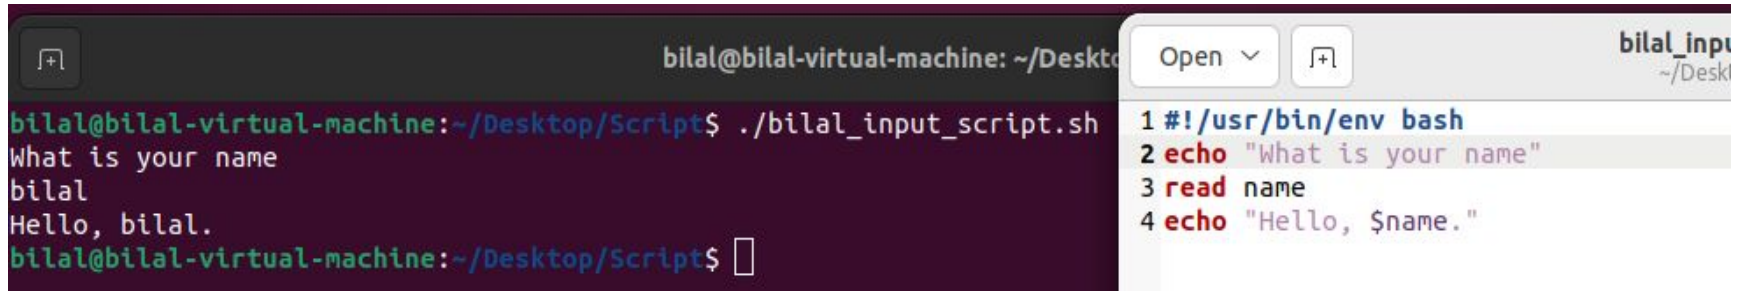

User Input

In Bash, you can get user input using the read command. The read command reads a line of input from the user and stores it in a variable.

Example	Command
Basic Syntax for read user inputs	<code>read variable_name</code>
to prompt the user for their name and store it in a variable called "name", you would use the following command	<code>read name</code>
You can also provide a prompt for the user by including a message before the read command, like this	<code>read -p "Enter your name: " name</code>

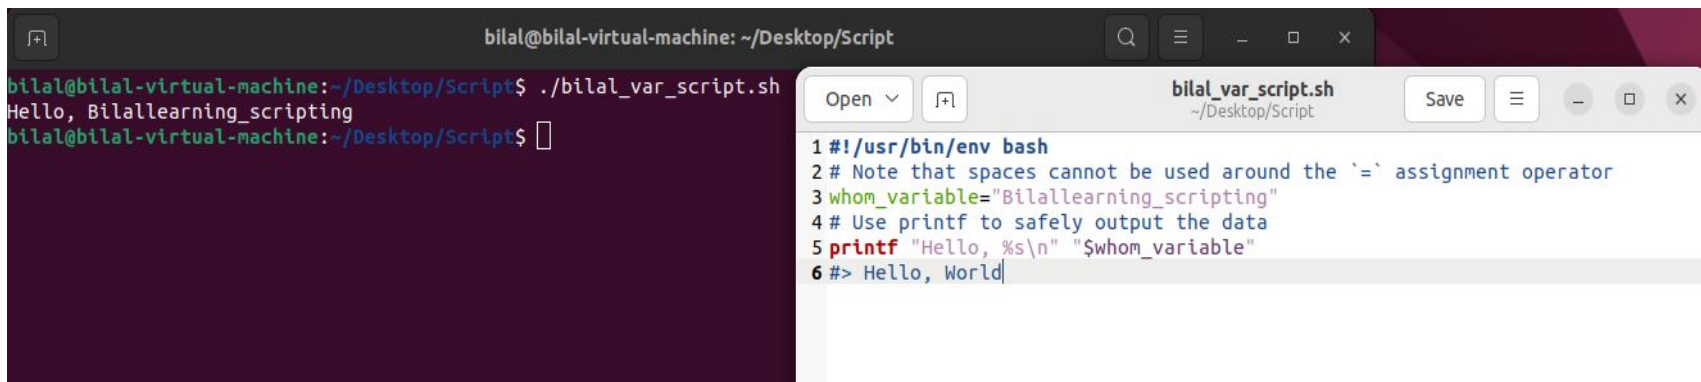

Hello World with User Input

The image shows a terminal window and a script editor. The terminal window, titled 'bilal@bilal-virtual-machine: ~/Desktop', shows the execution of a script. The prompt is 'bilal@bilal-virtual-machine:~/Desktop/Script\$'. The user enters './bilal_input_script.sh'. The script prompts 'What is your name', the user enters 'bilal', and the script outputs 'Hello, bilal.'. The prompt returns to 'bilal@bilal-virtual-machine:~/Desktop/Script\$'. The script editor, titled 'bilal_input_script.sh', shows the following code:

```
1 #!/usr/bin/env bash
2 echo "What is your name"
3 read name
4 echo "Hello, $name."
```

Hello World Using Variables

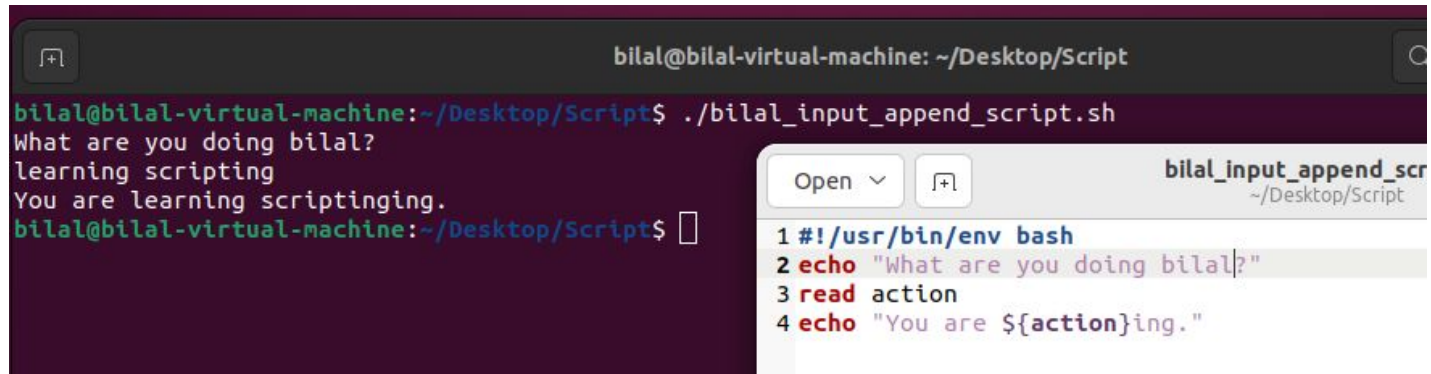

The image shows a terminal window and a code editor window. The terminal window, titled 'bilal@bilal-virtual-machine: ~/Desktop/Script', shows the execution of a script named 'bilal_var_script.sh'. The output of the script is 'Hello, Bilallearning_scripting'. The code editor window, titled 'bilal_var_script.sh ~/Desktop/Script', shows the contents of the script. The script is a bash script that sets a variable 'whom_variable' to 'Bilallearning_scripting' and uses 'printf' to output 'Hello, %s\n' with the value of 'whom_variable'. The script is currently at line 6, which contains 'Hello, World'.

```
bilal@bilal-virtual-machine: ~/Desktop/Script
bilal@bilal-virtual-machine:~/Desktop/Script$ ./bilal_var_script.sh
Hello, Bilallearning_scripting
bilal@bilal-virtual-machine:~/Desktop/Script$
```

```
1#!/usr/bin/env bash
2# Note that spaces cannot be used around the `=` assignment operator
3whom_variable="Bilallearning_scripting"
4# Use printf to safely output the data
5printf "Hello, %s\n" "$whom_variable"
6#> Hello, World
```

Append something to the variable value

The image shows a terminal window and a code editor. The terminal window, titled 'bilal@bilal-virtual-machine: ~/Desktop/Script', shows the execution of a script. The prompt is 'bilal@bilal-virtual-machine:~/Desktop/Script\$./bilal_input_append_script.sh'. The script outputs 'What are you doing bilal?', 'learning scripting', and 'You are learning scriptinging.'. The prompt is now 'bilal@bilal-virtual-machine:~/Desktop/Script\$'. The code editor, titled 'bilal_input_append_script' and located at '~/Desktop/Script', shows the script content:

```
1 #!/usr/bin/env bash
2 echo "What are you doing bilal?"
3 read action
4 echo "You are ${action}ing."
```

Importance of Quoting in Strings

Quoting is important for string expansion in bash. With these, you can control how the bash parses and expands your strings.

There are two types of quoting:

- **Weak:** uses double quotes: "
- **Strong:** uses single quotes: '

```
#!/usr/bin/env bash
world="World"
echo "Hello $world"
#> Hello World
```

```
#!/usr/bin/env bash
world="World"
echo 'Hello $world'
```

You can also use escape to prevent expansion:

```
#!/usr/bin/env bash
world="World"
echo "Hello \$world"
#> Hello $world
```

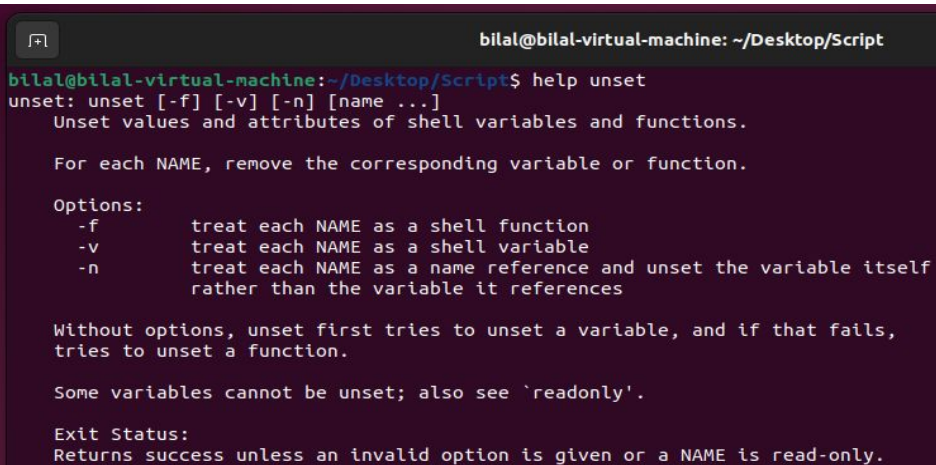

Viewing information for Bash built-ins

`help <command>`

This will display the Bash help (manual) page for the specified built-in.

For example, help unset will show:

```
bilal@bilal-virtual-machine: ~/Desktop/Script
bilal@bilal-virtual-machine:~/Desktop/Script$ help unset
unset: unset [-f] [-v] [-n] [name ...]
  Unset values and attributes of shell variables and functions.

  For each NAME, remove the corresponding variable or function.

Options:
  -f      treat each NAME as a shell function
  -v      treat each NAME as a shell variable
  -n      treat each NAME as a name reference and unset the variable itself
          rather than the variable it references

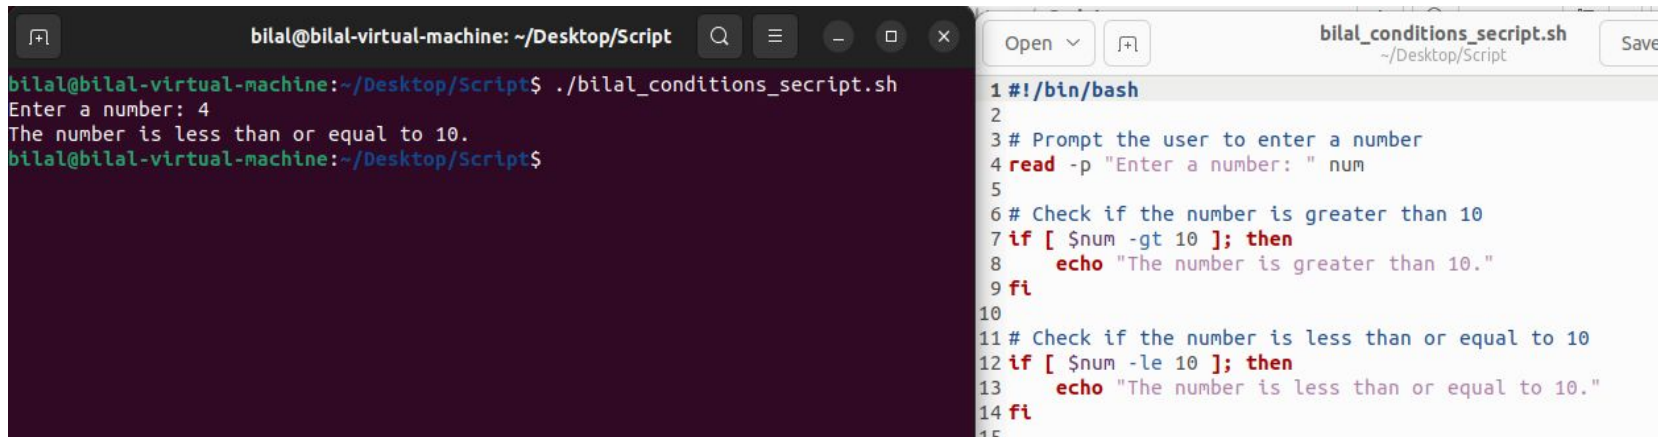

Without options, unset first tries to unset a variable, and if that fails,
tries to unset a function.

Some variables cannot be unset; also see 'readonly'.

Exit Status:
Returns success unless an invalid option is given or a NAME is read-only.
```

Conditionals : if

In Bash, conditional statements are used to control the flow of execution in a script based on certain conditions. The two main types of conditional statements are if statements and case statements.

```
bilal@bilal-virtual-machine: ~/Desktop/Script
bilal@bilal-virtual-machine:~/Desktop/Script$ ./bilal_conditions_secript.sh
Enter a number: 4
The number is less than or equal to 10.
bilal@bilal-virtual-machine:~/Desktop/Script$
```

```
1 #!/bin/bash
2
3 # Prompt the user to enter a number
4 read -p "Enter a number: " num
5
6 # Check if the number is greater than 10
7 if [ $num -gt 10 ]; then
8     echo "The number is greater than 10."
9 fi
10
11 # Check if the number is less than or equal to 10
12 if [ $num -le 10 ]; then
13     echo "The number is less than or equal to 10."
14 fi
15
```

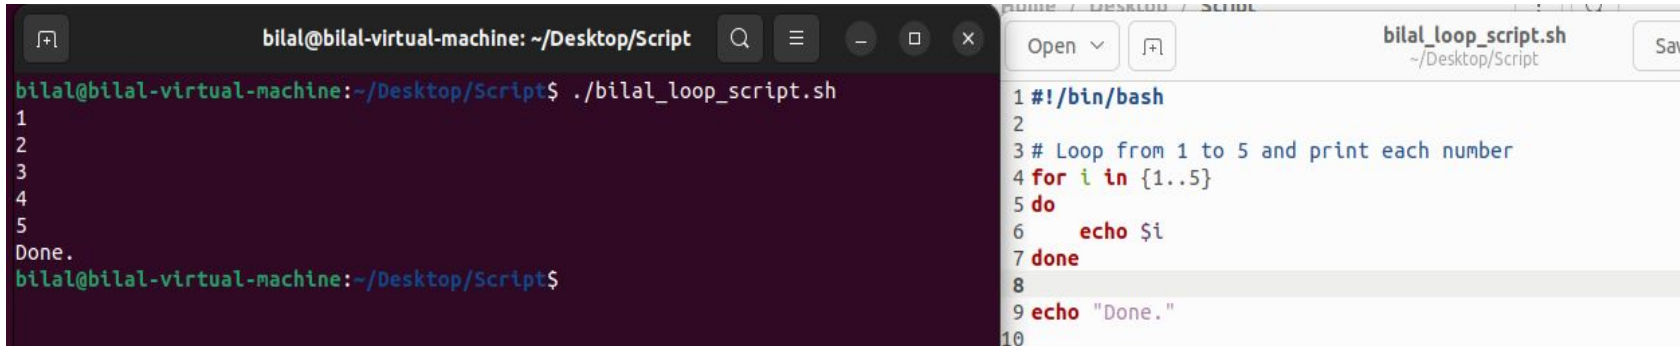

Conditionals : elif

```
bilal@bilal-virtual-machine: ~/Desktop/Script
bilal@bilal-virtual-machine:~/Desktop/Script$ ./bilal_condition1_script.sh
Enter a number: 7
The number is less than 10.
bilal@bilal-virtual-machine:~/Desktop/Script$
```

```
bilal_condition1_script.sh
~/Desktop/Script
1 #!/bin/bash
2
3 # Prompt the user to enter a number
4 read -p "Enter a number: " num
5
6 # Check if the number is greater than 10
7 if [ $num -gt 10 ]; then
8     echo "The number is greater than 10."
9 elif [ $num -eq 10 ]; then
10    echo "The number is equal to 10."
11 else
12    echo "The number is less than 10."
13 fi
14
```

Loop

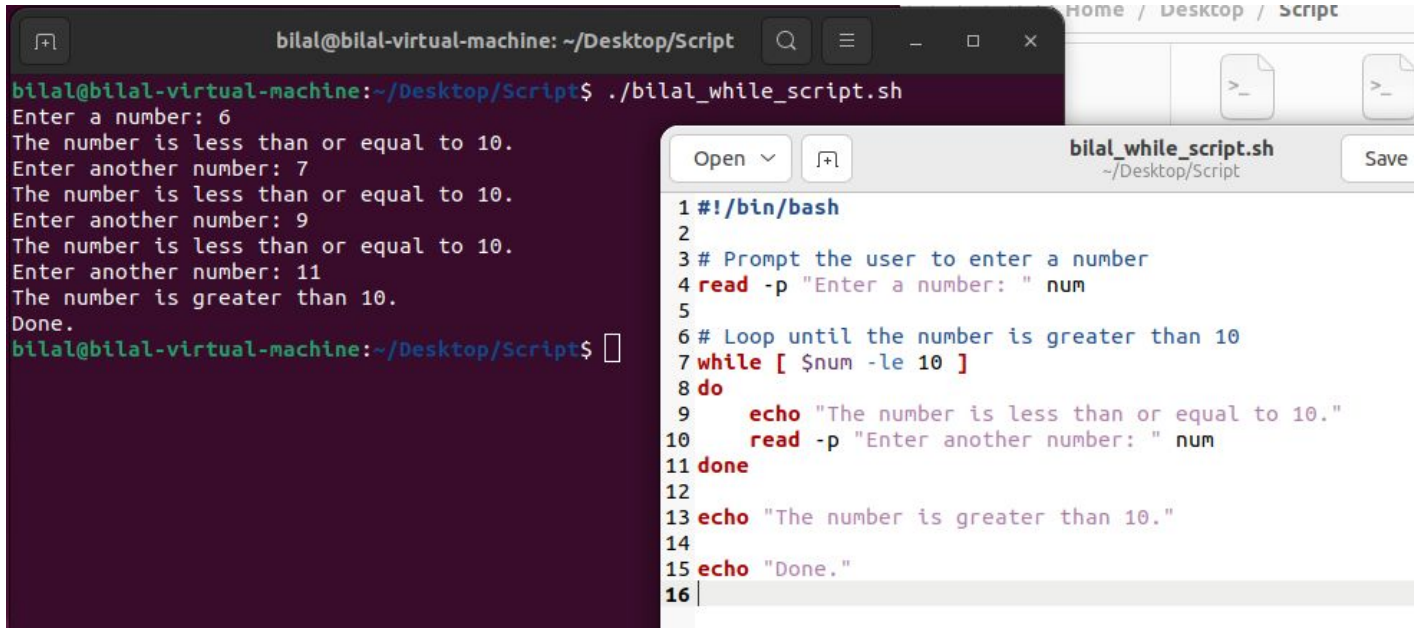

In Bash scripting, loops are used to repeat a block of code a certain number of times, or until a certain condition is met. There are two main types of loops in Bash: for loops and while loops.

The image shows a terminal window and a script file. The terminal window, titled 'bilal@bilal-virtual-machine: ~/Desktop/Script', shows the execution of a script named 'bilal_loop_script.sh'. The output of the script is a list of numbers from 1 to 5, followed by 'Done.'. The script file, titled 'bilal_loop_script.sh' and located at '~/Desktop/Script', contains the following code:

```
1 #!/bin/bash
2
3 # Loop from 1 to 5 and print each number
4 for i in {1..5}
5 do
6     echo $i
7 done
8
9 echo "Done."
```

While

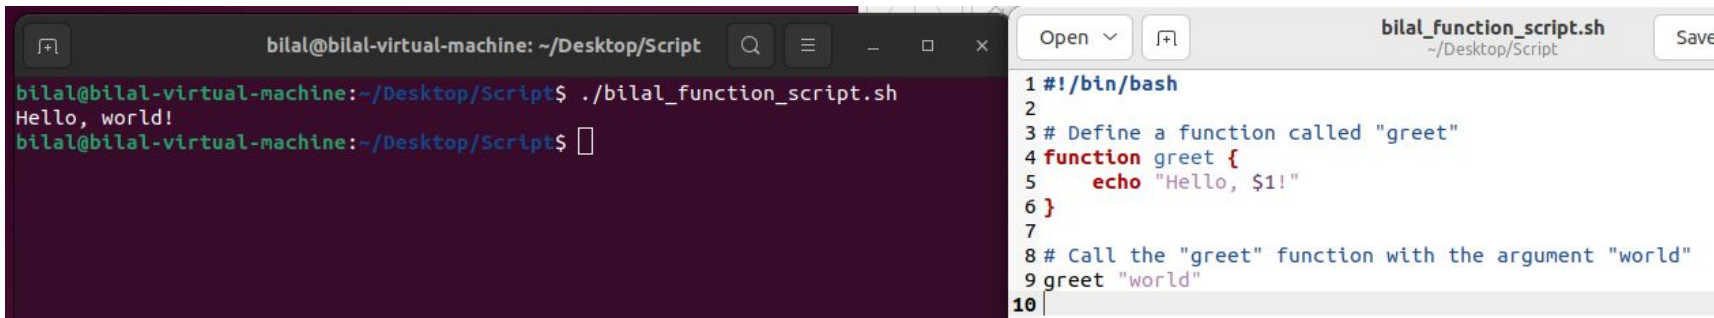

The image shows a terminal window and a script editor. The terminal window, titled 'bilal@bilal-virtual-machine: ~/Desktop/Script', shows the execution of a script named 'bilal_while_script.sh'. The script prompts the user to enter a number. For the first two inputs (6 and 7), the number is less than or equal to 10, and the script prints 'The number is less than or equal to 10.'. For the third input (9), the same message is printed. For the fourth input (11), the number is greater than 10, and the script prints 'The number is greater than 10.' and 'Done.'. The script editor, titled 'bilal_while_script.sh ~/Desktop/Script', shows the following code:

```
1#!/bin/bash
2
3# Prompt the user to enter a number
4read -p "Enter a number: " num
5
6# Loop until the number is greater than 10
7while [ $num -le 10 ]
8do
9    echo "The number is less than or equal to 10."
10    read -p "Enter another number: " num
11done
12
13echo "The number is greater than 10."
14
15echo "Done."
16
```

Functions

In Bash scripting, functions are blocks of code that can be called by name, and can optionally accept arguments and return values. Functions can be useful for encapsulating complex or repetitive tasks, and for breaking up large scripts into smaller, more manageable pieces.

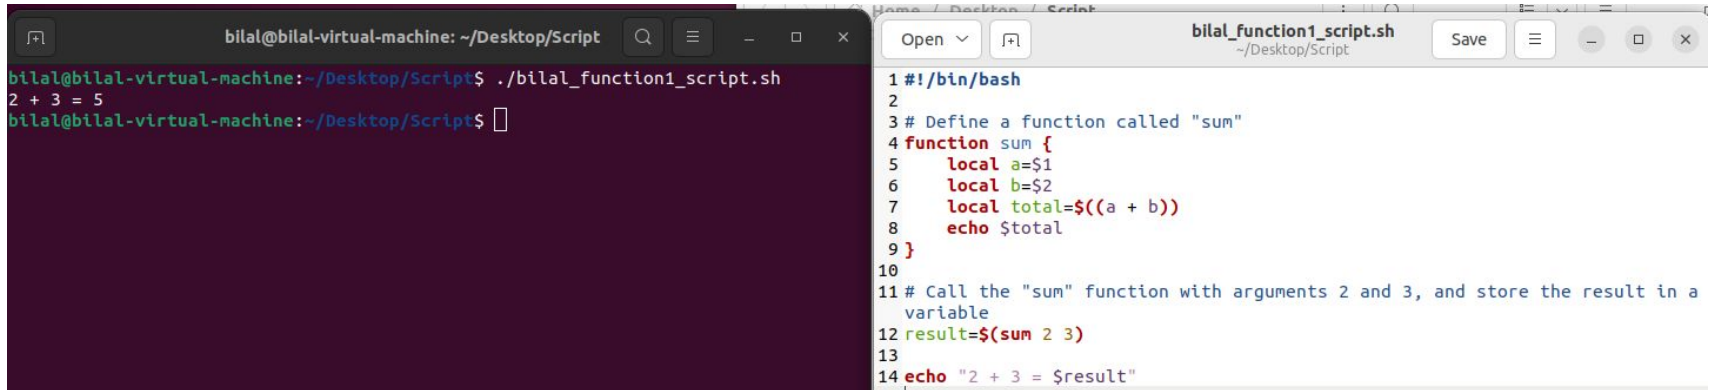

The image shows a terminal window and a code editor side-by-side. The terminal window, titled 'bilal@bilal-virtual-machine: ~/Desktop/Script', shows the execution of a script: `bilal@bilal-virtual-machine:~/Desktop/Script$./bilal_function_script.sh`, which outputs 'Hello, world!'. The code editor, titled 'bilal_function_script.sh', shows the script's content: a shebang line, a comment, a function definition for 'greet' that echoes its argument, and a call to the 'greet' function with the argument 'world'.

```
bilal@bilal-virtual-machine: ~/Desktop/Script
bilal@bilal-virtual-machine:~/Desktop/Script$ ./bilal_function_script.sh
Hello, world!
bilal@bilal-virtual-machine:~/Desktop/Script$

1#!/bin/bash
2
3# Define a function called "greet"
4function greet {
5    echo "Hello, $1!"
6}
7
8# Call the "greet" function with the argument "world"
9greet "world"
10
```

Example

The image shows two overlapping windows. The left window is a terminal with a dark purple background, showing the execution of a script. The right window is a script editor with a light gray background, showing the source code of the script.

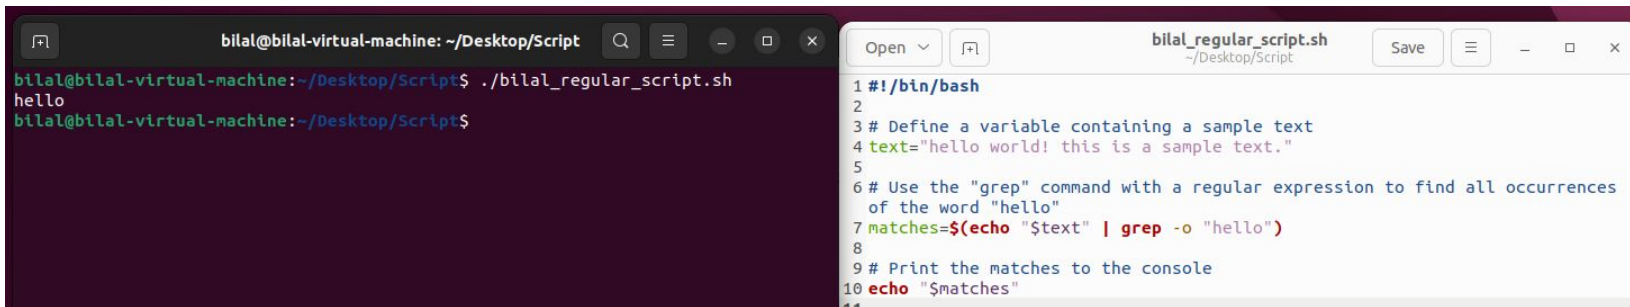

```
bilal@bilal-virtual-machine: ~/Desktop/Script
bilal@bilal-virtual-machine:~/Desktop/Script$ ./bilal_function1_script.sh
2 + 3 = 5
bilal@bilal-virtual-machine:~/Desktop/Script$
```

```
1#!/bin/bash
2
3# Define a function called "sum"
4function sum {
5    local a=$1
6    local b=$2
7    local total=$((a + b))
8    echo $total
9}
10
11# Call the "sum" function with arguments 2 and 3, and store the result in a
   variable
12result=$(sum 2 3)
13
14echo "2 + 3 = $result"
```

Regular expressions

Regular expressions, or "regex" for short, are patterns of characters that are used to search, match, and manipulate text. In Bash scripting, regular expressions are commonly used with the `grep`, `sed`, and `awk` commands to process text files and streams.

Here's an example of a simple regular expression that matches any string that contains the word "hello"

```
bilal@bilal-virtual-machine: ~/Desktop/Script
bilal@bilal-virtual-machine:~/Desktop/Script$ ./bilal_regular_script.sh
hello
bilal@bilal-virtual-machine:~/Desktop/Script$
```

```
1#!/bin/bash
2
3# Define a variable containing a sample text
4text="hello world! this is a sample text."
5
6# Use the "grep" command with a regular expression to find all occurrences
  of the word "hello"
7matches=$(echo "$text" | grep -o "hello")
8
9# Print the matches to the console
10echo "$matches"
11
```
